Abstract

An interaction integral method for evaluating \( T \)-stress and mixed-mode stress intensity factors (SIFs) for two-dimensional crack problems using the symmetric Galerkin boundary element method is presented. By introducing a known auxiliary field solution, the SIFs for both mode I and mode II are obtained from a path-independent interaction integral entirely based on the \( J(= J_1) \) integral. The \( T \)-stress can be calculated directly from the interaction integral by simply changing the auxiliary field. The numerical implementation of the interaction integral method is relatively simple compared to other approaches and the method yields accurate results. A number of numerical examples with available analytical and numerical solutions are examined to demonstrate the accuracy and efficiency of the method.

Keywords: Fracture mechanics; Mixed-mode stress intensity factors; \( T \)-stress; Symmetric Galerkin boundary element method; Interaction integral (M-integral); Two-state integral

1. Introduction

Fracture behaviour is generally characterized by a single parameter such as the stress intensity factors (SIFs) or path-independent \( J \)-integral [1]. These quantities provide a measure of the dominant behaviour of the stress field in the vicinity of a crack-tip. In order to understand the effect of the structural and loading configuration on the ‘constraint’ [2] conditions at the crack-tip, another parameter is required. A second fracture parameter often used is the elastic \( T \)-stress. In two dimensions, the \( T \)-stress is defined as a constant stress acting parallel to the crack and its magnitude is proportional to the nominal stress in the vicinity of the crack. Various studies have shown that the \( T \)-stress has significant influence on crack growth direction, crack growth stability, crack-tip constraint and fracture toughness [3–8]. In order to calculate the \( T \)-stress, researchers have used several techniques such as the stress substitution method [9], the variational method [10], the Eshelby \( J \)-integral method [11,12], the weight function method [13], the line spring method [14], the Betti–Rayleigh reciprocal theorem [15,16], and the interaction integral method [15,17]. Among these methods, the Eshelby \( J \)-integral method, the Betti–Rayleigh reciprocal theorem and the interaction integral method are based on path-independent integrals. In these methods, the fracture parameters can be calculated using data remote from the crack-tip and, as a result, higher accuracy compared to local methods can be achieved.

For a few idealized cases, analytical solutions for \( T \)-stress and SIFs are available. However, for practical problems involving finite geometries with complex loading, numerical methods need to be employed. The boundary element method (BEM) has emerged as a powerful numerical method for computational fracture analysis. In BEM analysis, only the boundary of the domain is discretized and unknown quantities are determined only on the boundaries. Compared to domain-type methods (e.g. finite element method (FEM) and meshless methods [18]), this boundary method significantly reduces the problem size and the problem setup. Additionally, remeshing of propagating cracks, which only involves local operations on
the propagating tip/front region, is simple and easy. The Galerkin BEM has several advantages over the collocation BEM. The biggest advantage is that the hypersingular integrals can be evaluated using standard C⁰ elements without any compromise or ambiguity [19]. Moreover, the weighted averaging formula in the Galerkin BEM provides a reliable solution in the neighborhood of geometric discontinuities such as corners and junctions. The Galerkin approach involves one more integration compared to collocation. The symmetric Galerkin BEM (SGBEM) uses both the standard singular displacement boundary integral equation (BIE) and the hypersingular traction BIE in such a way that the resultant coefficient matrix for the linear system becomes symmetric. The symmetry property of the coefficient matrix reduces the computation time of the problem. Also by exploiting symmetry [20] and using faster algorithms [21] in setting up the coefficient matrix, computational effort can be further reduced. This paper is based on the SGBEM [22–25], and follows the approach of Ref. [26]. A recent review [19] provides an excellent introduction to the literature on the SGBEM.

The interaction integral method is based on conservation laws of elasticity and fundamental relationships in fracture mechanics [27]. SIFs pertaining to mixed-mode fracture problems can be easily obtained from this integral. The basis of the approach lies in the construction of a conservation integral for two superimposed states (actual and auxiliary) of a cracked elastic solid. The analysis requires integration along a suitably selected path surrounding the crack-tip. The method was originally proposed by Chen and Shield [27], and later implemented numerically by Yau et al. [28] using the FEM applied to homogenous isotropic materials. Since then, this method has been used by many other researchers. For instance, Wang et al. [29] applied the method to anisotropic materials, and Gosz and Moran [30] investigated three-dimensional (3D) interface cracks. Recently this method has been widely used to determine mixed-mode SIFs in functionally graded materials (FGMs). Dolbow and Gosz [31] originally developed it with the extended FEM (X-FEM). Rao and Rahman [32] implemented this method using the element free Galerkin (EFG) method. Kim and Paulino [33,34] used the method to solve mixed-mode crack problems in isotropic and orthotopic FGMs in conjunction with the FEM and micromechanics models. They have also extended the two-state integral approach to evaluate T-stress in isotropic [35,36] and orthotropic [37] FGMs.

In the BEM literature, the displacement correlation technique (DCT) is widely used to evaluate SIFs due to its simplicity in numerical implementation [38]. Among the path-independent integral techniques, Aliabadi [39] applied the J-integral to mixed-mode crack problems by decoupling the J into its symmetrical and anti-symmetrical portions. Sladek and Sladek [40] used the conservation integral method in thermoelasticity problems to calculate the T-stress, and the J-integral to calculate the SIFs. Denda [41] implemented the interaction integral for mixed-mode analysis of multiple cracks in anisotropic solids using a dislocation and point force approach (Lekhnitskii–Eshelby–Stroh formalism). Wen and Aliabadi [42] proposed a different contour integral based on Westergaard’s solution and Betti’s reciprocal theorem to calculate the SIFs. Reviews of the application of the BEM in fracture can be found in Refs. [43,44]. In this paper, we develop a unified scheme by using the interaction integral method for calculating both the T-stress and the SIFs for mixed-mode cracks by means of the SGBEM. Recently, Gray et al. [26] proposed a modified quarter-point element for a more accurate representation of the crack opening displacement. The present methodology also includes this improved crack-tip element.

The remaining sections of this paper are organized as follows. Section 2 provides the definition of the T-stress. The interaction integral (called M-integral) method for calculating the fracture parameters is described in Section 3. Section 4 gives an introduction to the SGBEM, followed by the SG formulation for fracture and selected features of the modified quarter-point element. Section 5 presents various numerical examples in which the T-stress and the SIFs are evaluated by means of the M-integral. Finally, Section 6 concludes with some closing remarks and potential extensions. The Appendices A–D supplement the paper.

2. Fracture parameters: T-stress and stress intensity factors

Williams’ asymptotic solution [45] for crack-tip stress fields in any linear elastic body is given by a series of the form

\[ \sigma_{ij}(r, \theta) = A_1 r^{-1/2} f^{(1)}_{ij}(\theta) + A_2 r^{1/2} f^{(2)}_{ij}(\theta) + A_3 r^{3/2} f^{(3)}_{ij}(\theta) + \text{higher order terms}, \]  

where \( \sigma_{ij} \) is the stress tensor, \( r \) and \( \theta \) are polar coordinates with the origin at the crack-tip as shown in Fig. 1, \( f^{(1)}_{ij}, f^{(2)}_{ij}, f^{(3)}_{ij} \) are universal functions of \( \theta \), and \( A_1, A_2, A_3 \) are parameters proportional to the remotely applied loads. In the vicinity of the crack \( (r \to 0) \), the leading term which exhibits a square-root singularity dominates. The amplitude of the singular stress fields is characterized by the stress intensity factors (SIFs), i.e.

\[ \sigma_{ij} = \frac{K_I}{\sqrt{2\pi r}} f^I_{ij}(\theta) + \frac{K_II}{\sqrt{2\pi r}} f^{II}_{ij}(\theta), \]

where \( K_I \) and \( K_{II} \) are the mode I and mode II SIFs, respectively.

The second term in the Williams’ series solution (Eq. (1)) is a non-singular term, which is defined as the elastic T-stress. Thus, the above expression (2) can be expanded to
include this term as follows:

$$\sigma_{ij} = \frac{K_1}{\sqrt{2\pi r}} f_1^{ij}(\theta) + \frac{K_2}{\sqrt{2\pi r}} f_2^{ij}(\theta) + T \delta_{ij} \delta_{rl},$$  \hspace{1cm} (3)$$

The $T$-stress varies with different crack geometries and loadings. It plays a dominant role on the shape and size of the plastic zone, the degree of local crack-tip yielding, and also in quantifying fracture toughness. For mixed-mode problems, the $T$-stress contributes to the tangential stress and, as a result, it affects the crack growth criteria. By normalizing the $T$-stress with the applied load $\sigma_a(=K_{1a}/\sqrt{\pi a})$, a non-dimensional parameter $B$ can be defined by [2,10]

$$B = T/\sqrt{\pi a \alpha K_1},$$  \hspace{1cm} (4)$$

where $\alpha$ is the crack length. The dependence on geometrical configurations can be best indicated by the biaxiality parameter $B$.

3. The two-state interaction integral: $M$-integral

The interaction integral or $M$-integral is derived from the path-independent $J$-integral [1] for two admissible states of a cracked elastic FGM body. The formulation of the $M$-integral is presented here by techniques to calculate $T$-stress and SIFs. Finally, some aspects of the numerical scheme adopted for the implementation of the contour integral are discussed.

3.1. Basic formulation

The path-independent $J$-integral [1] is defined as

$$J = \lim_{\Gamma \to 0} \int_{\Gamma} (\nabla \cdot \delta_{ij} - \sigma_{ij} u_{i,1}) n_j \, d\Gamma,$$  \hspace{1cm} (5)$$

where $\nabla$ is the strain energy density given by

$$\nabla = \int_0^{r_0} \sigma_{ij} \, d\epsilon_{ij},$$  \hspace{1cm} (6)$$

and $n_j$ denotes the outward normal vector to the contour $\Gamma$, as shown in Fig. 1.

If two independent admissible fields are considered where the displacements, strains and stresses of the actual fields and the auxiliary fields are denoted by $(\mathbf{u}, \mathbf{e}, \sigma)$ and $(\mathbf{u}^\text{aux}, \mathbf{e}^\text{aux}, \sigma^\text{aux})$, respectively, then the $J$-integral of the superimposed fields (actual and auxiliary) can be written as:

$$J = \int_{\Gamma} \left\{ \frac{1}{2} (\sigma_{ik} + \sigma_{ik}^\text{aux}) (\epsilon_{ik} + \epsilon_{ik}^\text{aux}) \delta_{ij} - \left( \sigma_{ij} + \sigma_{ij}^\text{aux} \right) \right\} n_j \, d\Gamma.$$  \hspace{1cm} (7)$$

This integral can be conveniently decomposed into

$$J = J + J^\text{aux} + M,$$  \hspace{1cm} (8)$$

where $J$ is given by Eq. (5), $J^\text{aux}$ is given by

$$J^\text{aux} = \int_{\Gamma} (\nabla^\text{aux} \cdot \delta_{ij} - \sigma_{ij}^\text{aux} u_{i,1}^\text{aux} n_j) \, d\Gamma,$$  \hspace{1cm} (9)$$

with

$$\nabla^\text{aux} = \int_0^{r_0} \sigma_{ij}^\text{aux} \, d\epsilon_{ij}^\text{aux},$$  \hspace{1cm} (10)$$

and $M$ is the interaction integral involving the cross terms of actual and auxiliary fields, which is given by

$$M = \int_{\Gamma} \left\{ \frac{1}{2} (\sigma_{ik} e_{ik}^\text{aux} + \sigma_{ik}^\text{aux} e_{ik}) \delta_{ij} - \left( \sigma_{ij} u_{i,1}^\text{aux} + \sigma_{ij}^\text{aux} u_{i,1} \right) \right\} n_j \, d\Gamma.$$  \hspace{1cm} (11)$$

The $M$-integral deals with interaction terms only, and will be used directly for solving mixed-mode fracture mechanics problems.

3.2. Auxiliary fields for $T$-stress

The auxiliary fields are judiciously chosen for the interaction integral depending on the nature of the problem to be solved. Since the $T$-stress is a constant stress that is parallel to the crack, the auxiliary stress and displacement fields are chosen due to a point force $f$ in the $x_1$ direction (locally), applied to the tip of a semi-infinite crack in an infinite homogeneous body, as shown in Fig. 2(a).
The auxiliary stresses are given by Michell’s solution [46]:

\[
\sigma_{11}^{\text{aux}} = -\frac{f}{\pi r} \cos^3 \theta, \quad \sigma_{22}^{\text{aux}} = -\frac{f}{\pi r} \cos \theta \sin^2 \theta, \\
\sigma_{12}^{\text{aux}} = -\frac{f}{\pi r} \cos^2 \theta \sin \theta.
\]  

(12)

The corresponding auxiliary displacements are [47]

\[
\begin{align*}
\varepsilon_1^{\text{aux}} &= -\frac{f(1 + \kappa) }{8 \pi \mu} \ln r \frac{d}{dr} - \frac{f}{4 \pi \mu} \sin^2 \theta \\
\varepsilon_2^{\text{aux}} &= -\frac{f(\kappa - 1) }{8 \pi \mu} \theta + \frac{f}{4 \pi \mu} \sin \theta \cos \theta
\end{align*}
\]

(13)

where \(d\) is the coordinate of a fixed point on the \(x_1\) axis (see Fig. 2(a)), \(\mu\) is the shear modulus, and

\[
\kappa = \begin{cases} 
(3 - \nu)(1 + \nu) & \text{plane stress} \\
(3 - 4\nu) & \text{plane strain}.
\end{cases}
\]

(14)

### 3.3. Determination of T-stress

By considering the auxiliary field in Eq. (12), a simple expression for the \(T\)-stress in terms of the interaction integral \((M)\), the point force for the auxiliary field \((f)\), and material properties \((E, \nu)\) can be obtained. Since the modulus of elasticity is same for both the actual and the auxiliary states, the stresses are

\[
\sigma_{ij} = C_{ijkl} e_{kl} \quad \text{and} \quad \sigma_{ij}^{\text{aux}} = C_{ijkl} e_{kl}^{\text{aux}},
\]

(15)

where \(C_{ijkl}\) is the constitutive tensor. Then, from Eq. (15)

\[
\sigma_{ij} e_{kl}^{\text{aux}} = \sigma_{ij}^{\text{aux}} e_{kl}.
\]

(16)

Therefore, Eq. (11) can be rewritten as

\[
M = \int_{\Gamma} \left( (\sigma_{ij} e_{kl}^{\text{aux}} \delta_{ij} - (\sigma_{ij}^{\text{aux}} u_{1i} + \sigma_{ij}^{\text{aux}} u_{1j}) n_j) d\Gamma. \right.
\]

(17)

The \(M\)-integral is path-independent, and thus any arbitrary path can be chosen to evaluate the integral. The actual stress field is composed of singular terms, \(T\)-stress term and higher order terms (see Eqs. (1) and (3)). Considering a circular integration path, if \(r^\prime\) shrinks to zero (\(r \rightarrow 0\)), then the contribution of the higher order terms tends to zero. The coefficients of the singular terms \(O(1/r^2)\) after the integration over \(\theta\) from \(-\pi\) to \(+\pi\) in Eq. (17) sum to zero (see Appendix D). As a result, the only contribution to the \(M\)-integral comes from the \(T\)-stress term. Hence, the only stress to be considered is in the crack direction, i.e.

\[
\sigma_{ij} = T \delta_{ij} \delta_{ij},
\]

(18)

or \(\sigma_{11} = T\). By means of Eq. (18), the stress–strain and strain–displacement relationships are

\[
u_{1,1} = \frac{E}{E'} \quad \text{and} \quad \varepsilon_{11}^{\text{aux}} = \varepsilon_{11}^{\text{aux}}.
\]

(19)

Thus, the first two terms of Eq. (17) cancel out and we get

\[
M = -\lim_{r^\prime \to 0} \int_{\Gamma} \sigma_{ij}^{\text{aux}} n_j u_{1i} d\Gamma = -\frac{T}{E'} \lim_{r^\prime \to 0} \int_{\Gamma} \sigma_{ij}^{\text{aux}} n_j d\Gamma.
\]

(20)

In the auxiliary state, the force \(f\) is in equilibrium (see Fig. 2(a)), thus

\[
f = -\lim_{r^\prime \to 0} \int_{\Gamma} \sigma_{ij}^{\text{aux}} n_j d\Gamma,
\]

(21)

and by substituting back into Eq. (20), we obtain

\[
T = \frac{E'}{f} M
\]

(22)

where

\[
E' = \begin{cases} 
E & \text{plane stress} \\
E/(1 - \nu^2) & \text{plane strain}.
\end{cases}
\]

(23)

By calculating the \(M\)-integral from Eq. (17) and plugging the value in Eq. (22), the \(T\)-stress can be readily obtained.
3.4. Auxiliary fields for SIFs

The mixed-mode SIFs can be extracted from the interaction integral, Eq. (11), through an appropriate definition of auxiliary fields. Local Cartesian and polar coordinates originate from the crack-tip (see Fig. 1). According to Fig. 2(b), the auxiliary stress fields (expressed in polar coordinates) are given by

\[ \sigma_{ij}^{\text{aux}} = \frac{K_{i}^{\text{aux}}}{\sqrt{2\pi r}} f_{i}^j(\theta) + \frac{K_{II}^{\text{aux}}}{\sqrt{2\pi r}} f_{i}^{II}(\theta), \quad (i,j = 1, 2) \]  

(24)

where the angular functions \( f_{i}^j(\theta) \) are given in Appendix A. The corresponding auxiliary displacement fields are given by

\[ u_{i}^{\text{aux}} = \frac{K_{i}^{\text{aux}}}{\mu} \sqrt{\frac{r}{2\pi}} g_{i}^j(\theta) + \frac{K_{II}^{\text{aux}}}{\mu} \sqrt{\frac{r}{2\pi}} g_{i}^{II}(\theta), \]  

(25)

\((i = 1, 2)\)

where \( \mu \) is the shear modulus, and \( K_{i}^{\text{aux}} \) and \( K_{II}^{\text{aux}} \) are the auxiliary mode I and mode II SIFs, respectively. The angular functions \( g_{i}^j(\theta) \) are also given in Appendix A. These angular functions can be found in many references on fracture mechanics, e.g. the textbook by Anderson [2] or Hills et al. [48].

3.5. Determination of SIFs

The relationship among the \( J \)-integral and the mode I and mode II stress intensity factors (SIFs) \( (K_{i} \) and \( K_{II} \)) is established as

\[ J = \frac{K_{I}^2 + K_{II}^2}{E'} \]  

(26)

where \( E' \) is given by Eq. (23). By superimposing the actual and auxiliary fields, and using Eq. (26), one obtains

\[ J^s = \left( \frac{(K_{I}^{\text{aux}})^2 + (K_{II}^{\text{aux}})^2}{E'} \right) = J^{\text{aux}} + J + M \]  

(27)

where

\[ J^{\text{aux}} = \left( \frac{(K_{I}^{\text{aux}})^2 + (K_{II}^{\text{aux}})^2}{E'} \right) \]  

(28)

and

\[ M = \frac{2}{E'} (K_{I} K_{I}^{\text{aux}} + K_{II} K_{II}^{\text{aux}}). \]  

(29)

The mode I SIF \( (K_{I}) \) is computed by assigning the SIFs of the auxiliary field to \( K_{I}^{\text{aux}} = 1.0 \) and \( K_{II}^{\text{aux}} = 0.0 \) in Eq. (29), i.e.

\[ K_{I} = \frac{E'}{2} M \ (K_{I}^{\text{aux}} = 1.0, \ K_{II}^{\text{aux}} = 0.0). \]  

(30)

Similarly, the mode II SIF \( (K_{II}) \) can be obtained by assigning \( K_{I}^{\text{aux}} = 0.0 \) and \( K_{II}^{\text{aux}} = 1.0 \) in Eq. (29), i.e.

\[ K_{II} = \frac{E'}{2} M \ (K_{I}^{\text{aux}} = 0.0, \ K_{II}^{\text{aux}} = 1.0). \]  

(31)

The \( M \)-integral in Eqs. (30) and (31) is evaluated by means of Eq. (11) and the auxiliary fields given by Eqs. (24) and (25).

4. Symmetric Galerkin boundary element method

The basic symmetric Galerkin BEM (SGBEM) framework for two-dimensional (2D) elastic boundary value problems is introduced in this section. First, the algorithm for bodies without cracks is provided. Then, the fracture work for two-dimensional (2D) elastic boundary value problems is introduced in this section. First, the algorithm is developed followed by a section on crack-tip elements.

4.1. Basic SGBEM formulation for 2D elasticity

The boundary integral equation (BIE) for a source point \( P \) interior to the domain for linear elasticity without body forces [49] is given by

\[ u_{k}(P) - \int_{I_{S}} \left[ U_{ij}(P, Q) \tau_{i}(Q) - T_{kj}(P, Q) u_{j}(Q) \right] dQ = 0. \]  

(32)

where \( Q \) is a field point, \( \tau_{i} \) and \( u_{j} \) are traction and displacement vectors, respectively, \( U_{ij} \) and \( T_{kj} \) are the Kelvin kernel tensors and \( I_{S} \) denotes the boundary of the domain.

For plane strain problems (see, e.g. Ref. [49]), the Kelvin kernels are

\[ U_{ij} = \frac{1}{8\pi G(1 - \nu)} [r_{k} r_{j} - (3 - 4\nu) \delta_{ij} \ln(r)], \]  

(33)

\[ T_{kj} = -\frac{1}{4\pi(1 - \nu)r} \left[ (1 - 2\nu) \delta_{kj} + 2r_{k}^{'} r_{j}^{'} \frac{\delta r}{\delta n} \right] - (1 - 2\nu) (n_{k} r_{j} - n_{j} r_{k}), \]  

(34)

where \( \nu \) is Poisson’s ratio, \( G \) is shear modulus, \( \delta_{ij} \) is the Kronecker delta and

\[ r_{k} = x_{k}(Q) - x_{k}(P), \quad r^{2} = r_{i} r_{i}, \quad r_{k} = r_{k} / r \]  

and \( \delta r / \delta n = r_{k} n_{j} \).

For a point \( P \) interior to the domain, the displacement gradient can be obtained by differentiating Eq. (32) with respect to the source point \( P \). As \( P \) approaches the boundary, the limit of right-hand-side of Eq. (32) exists [25]. For \( P \in I_{B} \), the BIE is defined in the limiting sense. Substituting the displacement gradient into the Hooke’s law, we get
the HBIE for the boundary stresses

$$\sigma_{ij} (P) = \int_{\Gamma} [D_{ijkl}(P, Q) \tau_j(Q) - S_{ijkl}(P, Q) u_j(Q)] dQ = 0,$$

(36)

where the kernels are given by [49]

$$D_{ijkl} = \frac{1}{4\pi(1-\nu)} [(1-2\nu)(\delta_{ij}\delta_{kj} - \delta_{il}\delta_{kj}) - 2\delta_{ik}\delta_{lj}],$$

$$S_{ijkl} = \frac{G}{2\pi (1-\nu)} \left[ \frac{\partial}{\partial n} [(1-2\nu)(\delta_{ij}\delta_{kj} - \delta_{il}\delta_{kj}) - 2\delta_{ik}\delta_{lj}] - 4n_i r_j n_l - \delta_{ik} n_l - 4(1-\nu)\delta_{ij} n_l \right].$$

(37)

In the collocation approach, the BIE (32) and HBIE (36) are enforced at discrete source points. In a Galerkin approximation, the error in the approximate solution is orthogonalized against the shape functions. The shape functions are the weighting functions and the integral equations (32) and (36) are enforced in the ‘weak sense’, i.e.

$$\int_{\Gamma_b} \psi_m(P) \left[ u_b(P) - \int_{\Gamma_b} [U_{ijkl}(P, Q) \tau_j(Q) - T_{ijkl}(P, Q)] dQ \right] dP = 0,$$

(39)

$$\int_{\Gamma_c} \psi_m(P) \left[ \sigma_{ijkl} - \int_{\Gamma_c} [D_{ijkl}(P, Q) \tau_j(Q) - S_{ijkl}(P, Q) u_j(Q)] dQ \right] dP = 0,$$

(40)

respectively. As a result, the Galerkin technique possesses the important property of the local support. A symmetric coefficient matrix in the symmetric-Galerkin approximation can be obtained by using Eq. (39) on the boundary $\Gamma_{b(0)}$ where displacements $u_{b(0)}$ are prescribed, and using Eq. (40) on the boundary $\Gamma_{c(0)}$ with prescribed tractions $\tau_{b(0)}$ (see Fig. 3). Note that, $\Gamma_b = \Gamma_{b(0)} + \Gamma_{b(0)}$ for a well-posed boundary value problem.

The additional boundary integration is the key to obtaining a symmetric coefficient matrix, as this ensures that the source point $P$ and field point $Q$ are treated in the same manner in evaluating the kernel tensors $U_{ijkl}$, $T_{ijkl}$, $D_{ijkl}$ and $S_{ijkl}$. After discretization, the resulting equation system can be written in block-matrix form [25] as

$$\begin{bmatrix} H_{11} & H_{12} \\ H_{21} & H_{22} \end{bmatrix} \begin{bmatrix} u_{b(0)} \\ \tau_{b(0)} \end{bmatrix} = \begin{bmatrix} G_{11} & G_{12} \\ G_{21} & G_{22} \end{bmatrix} \begin{bmatrix} \tau_{b(0)} \\ \tau_{b(0)} \end{bmatrix}.$$

(41)

Here, the first and second rows represent, respectively, the BIE written on $\Gamma_{b(0)}$ and the HBIE written on $\Gamma_{b(0)}$. Further, $u_{c}$ and $\tau_{c}$ denote unknown displacement and traction vectors. Rearranging Eq. (41) into the form $[A][x] = [b]$, and multiplying the HBIE by $-1$, one obtains

$$\begin{bmatrix} -G_{11} & H_{12} \\ G_{21} & -H_{22} \end{bmatrix} \begin{bmatrix} \tau_{c} \\ u_{c} \end{bmatrix} = \begin{bmatrix} -H_{11} u_{b(0)} + G_{12} \tau_{b(0)} \\ H_{21} \tau_{b(0)} - G_{22} u_{b(0)} \end{bmatrix}.$$

(42)

The symmetry of the coefficient matrix, $G_{11} = G_{11}^T$, $H_{22} = H_{22}^T$, and $H_{12} = G_{12}^T$ now follows from the symmetry properties of the kernel tensors [25].

4.2. Fracture analysis with the SGBEM

The symmetric-Galerkin formulation for linear elastic fracture analysis is provided in this section. Consider a body of arbitrary shape $B$ which contains a crack, as shown in Fig. 3. The boundary $\Gamma$ of the body $B$ is composed of non-crack boundary $\Gamma_b$ and the crack surface $\Gamma_c$. The portion of the boundary $\Gamma_b$ with prescribed displacements is denoted by $\Gamma_{b(0)}$, and the portion with prescribed traction boundary is denoted by $\Gamma_{b(0)}$. The crack surface $\Gamma_c$ consists of two coincident surfaces $\Gamma_c^+$ and $\Gamma_c^-$, where $\Gamma_c^+$ and $\Gamma_c^-$ represent the upper and lower crack surfaces, respectively. The outward normals to the crack surfaces, designated by $n_c^+$ and $n_c^-$, are oriented in opposite directions and at any point on the crack $n_c^- = -n_c^+$. Since the only difference between the two coincident crack surfaces is the orientation of the normals ($n_c^+ = -n_c^-$), it is convenient to replace the displacements $u_c^+$ and $u_c^-$ by the single crack opening displacement $\Delta u_c = u_c^+ - u_c^-$, and the tractions $\tau_c^+$ and $\tau_c^-$ by the sum of tractions $\sum \tau_c = \tau_c^+ + \tau_c^-$. As a consequence, it suffices to discretize the upper crack surface $\Gamma_c^+$. Thus, the BIE and HBIE written for an interior point $P$ take the following form:

$$u_c(P) = \int_{\Gamma_b} [U_{ijkl}(P, Q) \tau_j(Q) - T_{ijkl}(P, Q) u_j(Q)] dQ + \int_{\Gamma_c^+} [D_{ijkl}(P, Q) \tau_j(Q) - S_{ijkl}(P, Q) u_j(Q)] dQ,$$

(43)

$$\sigma_{ij}(P) = \int_{\Gamma_b} [D_{ijkl}(P, Q) \tau_j(Q) - S_{ijkl}(P, Q) u_j(Q)] dQ + \int_{\Gamma_c^+} [D_{ijkl}(P, Q) \tau_j(Q) - S_{ijkl}(P, Q) u_j(Q)] dQ,$$

(44)
However, since the crack surfaces are usually symmetrically loaded, i.e. \( \tau_c = -\tau_c^+ \), one gets

\[
u_k(P) = \int_{\Gamma_c} \left[ U_{ij}(P, Q) \tau_j(Q) - T_{ij}(P, Q) u_j(Q) \right] dQ
\]

\[
- \int_{\Gamma_c} T_{ij}(P, Q) \Delta u_j(Q) dQ.
\]

(45)

\[
\sigma_j(P) = \int_{\Gamma_c} \left[ D_{ikm}(P, Q) \tau_{km}(Q) - S_{ikm}(P, Q) u_{km}(Q) \right] dQ
\]

\[
- \int_{\Gamma_c} S_{ikm}(P, Q) \Delta u_{km}(Q) dQ.
\]

(46)

Previous boundary element solutions of fracture mechanics problems in terms of displacement discontinuities have been presented by Crouch and co-workers [50,51]. In the Galerkin approximation for the non-crack boundary \( \Gamma_c \), the limit of Eqs. (45) and (46) is taken as \( P \to \Gamma_{bc} \) and \( \Gamma_{bc2} \), respectively. Since tractions are prescribed on the crack surface \( \Gamma_c^+ \), only Eq. (46) is written for source points on \( \Gamma_c^+ \) and, following the Galerkin approximation, the limit of Eq. (46) as \( P \to \Gamma_{bc}^+ \) is considered. Converting the stress equation (46) into a traction equation through the identity \( \tau_j(P) = \sigma_{ij}(P) n_j(P) \), with \( n_j(P) \) being the outward normal at \( P \) and discretizing, the following system is obtained from Eqs. (45) and (46) in block matrix form

\[
\begin{bmatrix}
H_{bb} & H_{bc} \\
H_{cb} & H_{cc}
\end{bmatrix}
\begin{bmatrix}
\Delta u_b \\
\Delta u_c
\end{bmatrix}
= \begin{bmatrix}
G_{bb} & 0 \\
G_{bc} & G_{cc}
\end{bmatrix}
\begin{bmatrix}
\tau_b \\
\tau_c
\end{bmatrix},
\]

where the subscripts \( b \) and \( c \) denote the contribution of the non-crack boundary and upper crack surface, respectively. For the present case, with traction free cracks \( \tau_c = 0 \), the system of equations reduces to

\[
\begin{bmatrix}
H_{bb} & H_{bc} \\
H_{cb} & H_{cc}
\end{bmatrix}
\begin{bmatrix}
\Delta u_b \\
\Delta u_c
\end{bmatrix}
= \begin{bmatrix}
G_{bb} & 0 \\
G_{bc} & G_{cc}
\end{bmatrix}
\begin{bmatrix}
\tau_b \\
0
\end{bmatrix}. \tag{47}
\]

The vector \( \tau_b \) is a mixture of known traction \( \tau_{bc} \) and unknown traction \( \tau_c \), similarly \( u_b \) is a mixture of known displacement \( u_{bc} \) and unknown displacement \( u_c \). Eq. (48) can be written in terms of the known and unknown boundary displacement and traction values as

\[
\begin{bmatrix}
H_{bb} & H_{bc} \\
H_{cb} & H_{cc}
\end{bmatrix}
\begin{bmatrix}
u_{bb} \\
u_{bc}
\end{bmatrix}
= \begin{bmatrix}
G_{bb} & 0 \\
G_{bc} & G_{cc}
\end{bmatrix}
\begin{bmatrix}
\tau_c \\
0
\end{bmatrix},
\]

\[
\begin{bmatrix}
G_{bb} & G_{bc} & 0 \\
G_{bc} & G_{bb} & 0 \\
G_{cb} & G_{cc} & 0
\end{bmatrix}
\begin{bmatrix}
\tau_c \\
0
\end{bmatrix} = \begin{bmatrix}
\Delta u_c
\end{bmatrix}.
\]

(49)

where the subscripts \( b, c \) and \( s \) represents the terms corresponding to the non-crack boundary with prescribed displacements \( \Gamma_{bc} \), non-crack boundary with prescribed tractions \( \Gamma_{bc2} \) and the crack surface \( \Gamma_c^+ \), respectively.

By rearranging Eq. (49) into the form \( [A] [x] = [b] \), and multiplying the BIEs by \( -1 \), we get the system of the matrix

\[
\begin{bmatrix}
-G_{bb,c} & H_{bb,c} & H_{bc,c} \\
G_{bb,b} & -H_{bb,b} & -H_{bc,b} \\
G_{cb,c} & -H_{cb,c} & -H_{cc,c}
\end{bmatrix}
\begin{bmatrix}
\tau_c \\
0
\end{bmatrix} = \begin{bmatrix}
-H_{bb,b} u_{bc} + G_{bb,b} \tau_{bc} \\
H_{bc,b} u_{bc} - G_{bc,b} \tau_{bc}
\end{bmatrix}.
\]

(50)

The final coefficient matrix of this system is symmetric due to the symmetric properties of the kernel tensors [25,52]. Further details can be found in Refs. [24,25,52–54].

4.3. Crack-tip elements

In fracture analysis, a quarter-point element at the crack-tip accounts for the \( \sqrt{r} \) displacement behaviour of the crack-tip, where \( r \) is the distance from the source point to the tip. The quarter-point element is formed from the standard quadratic element by simply moving the mid-node coordinates three-fourths of the way towards the crack-tip [55,56] (see Fig. 4). The modified quarter-point (MQP) crack-tip element [26] is based on the standard quarter-point element, but altered to account for a constraint on the linear term as suggested by Gray and Paulino [57]. This constraint is implemented in the modified shape functions by including a cubic term. Use of this element has been shown to greatly improve the accuracy in computed values for SIFs by means of local techniques [26]. The present algorithm makes use of all the crack-tip elements shown in Fig. 4.

The standard quadratic shape functions are defined in terms of the intrinsic coordinate \( t \in [0, 1] \) by

\[
\psi_1(t) = (1 - t)(1 - 2t), \quad \psi_2(t) = 4t(1 - t), \quad \psi_3(t) = t(2t - 1)
\]

and thus the boundary interpolation is

\[
\hat{\Gamma}(t) = \sum_{j=1}^{3} (x_j \psi_j(t), y_j \psi_j(t)). \tag{52}
\]

For the standard quarter-point crack-tip element, shown in Fig. 4, the mid-side node is moved to the quarter-point position. The effect of this is that \( t = \sqrt{r} \), which provides the singular behavior at the tip. For the modified quarter-point, the displacement discontinuity is given by

\[
\Delta u(t) = \sum_{j=2}^{3} (\Delta u_j \hat{\psi}_j(t), \Delta u_j \hat{\psi}_j(t)). \tag{53}
\]
where the new shape functions $\hat{\psi}$ are

$\hat{\psi}_1(t) = 4t(1-t) - 4t(1-t)(1-2t)/3 = -8t^3/3$,

$\hat{\psi}_2(t) = t(2t-1) + 2t(1-t)(1-2t)/3 = (4t^3 - t)/3$.

As the intrinsic coordinate $t$ is proportional to $\sqrt{r}$, the MQP element is seen to give crack opening displacements which are of the form $\Delta u_t = A\sqrt{r} + B\sqrt{r}^{1/2}$; the absence of the linear term in $r$ is consistent with the proof by Gray and Paulino [57]. It should be noted that the shape function $\psi_1(t)$ is not defined, as it multiplies the crack opening displacement at the tip which is known to be zero.

### 4.4. Numerical implementation of the $M$-integral

The accuracy of the computation of the $M$-integral depends on the integration points of the path and the method of integration. Integrals are evaluated along the circular path centered at the crack-tip as shown in Fig. 5.

The integration along the contour path can be performed by using simple trapezoidal rule or Gaussian quadrature formula. The contour integrals can be written as follows

$$M = \int_{\Gamma_r} F_N(x,y) d\Gamma, \quad (x,y) \in \Gamma$$

where $F_N$ denotes the integrand of Eq. (11) and $\Gamma_r$ is the integration path of interest. The following formula is used for the trapezoidal rule

$$\int_{\Gamma_r} F_N(x,y) d\Gamma = \frac{2\pi}{m} \sum_{n=1}^{2m} F_N h \cos \frac{\pi n}{m}, h \sin \frac{\pi n}{m}$$

where $h$ is the radius of the circular path. Alternatively Eq. (55) in polar $(r, \omega)$ coordinates is given by

$$M = h \int_{-\pi}^{\pi} F_N(r, \omega) d\omega.$$
(4) Fracture specimen configurations.
- Single edge notch tension (SENT) specimen.
- Single edge notch bending (SENB) specimen.
- Center cracked tension (CCT) or middle crack tension (MT) specimen.
- Double edge notch tension (DENT) specimen.

The first example is an inclined central crack in an infinite plate. This problem has analytical solution for both T-stress and SIFs. An edge crack in a finite plate is analysed in the second problem and compared with reference solutions. The third problem is an interesting problem consisting of two interacting cracks in a finite plate. The last example investigates the benchmark examples as used for laboratory experiments and provides solution for the T-stress, SIF and the associated biaxiality ratios. Unless otherwise stated, in all the examples we use modified quarter-point element at the crack-tips.

5.1. Infinite plate with an interior inclined crack

Consider a plate containing a single interior crack of length $2a$ oriented at an angle $\theta$ with the horizontal direction as shown in Fig. 6. The plate is loaded with a uniform far-field traction $\sigma = 1$ applied symmetrically in the vertical direction and $\lambda \sigma$ in the horizontal direction, where $\lambda$ is the lateral load ratio. The crack length is $2a = 2$ and the plate dimensions are $2H = 2W = 100$, which can be considered as an infinite domain. T-stress, $K_I$ and $K_{II}$ are calculated for various values of $\theta$ where $0 < \theta < \pi/2$. The boundary of the plate is discretized with only two quadratic elements on each side, and the crack is discretized with four elements. The number of Gauss points used for integration is $n = 8$. The Young’s modulus is taken as $E = 1.0$ (consistent units) and Poisson’s ratio is $\nu = 0.3$. The exact solutions of the SIFs and the T-stress for this problem [5] are

$$K_I = \sigma(\lambda \sin^2 \theta + \cos^2 \theta)\sqrt{\pi a}$$

$$K_{II} = \sigma(1 - \lambda) \cos \theta \sin \theta \sqrt{\pi a}$$

$$T = -(1 - \lambda) \sigma \cos 2\theta.$$  

The results of T-stress, normalized $K_I$ and $K_{II}$ for the right crack-tip and the corresponding analytical solution for $\lambda = 0$ (uniaxially loaded) and $\lambda = 0.5$ (biaxially loaded) are presented in Tables 1 and 2, respectively. The results show good agreement between numerical (SGBEM) and analytical (Eq. (59)) results.

The influence of several parameters, i.e. the radius of the integration contour $r$, the number of integration points $n$, crack discretization $m$, and the crack-tip elements on the calculated SIFs and the T-stress is studied next using the SGBEM.

5.1.1. Effect of the radius of the integration contour

The M-integral is evaluated along different circular integration paths as shown in Fig. 5. The $K_I$, $K_{II}$ and T-stress results are obtained for several circular paths at the right crack-tip with the radius of the circular contour $r$ ranging from $r = 0.025a$ (near crack-tip) to $r = 1.5a$ (closer to opposite crack-tip). According to Fig. 6, the crack angle is $\theta = 30^\circ$, and the lateral load ratio is $\lambda = 0$. The outer boundary of the plate is discretized with only two quadratic

5.1.2. Effect of the number of integration points

A convergence study with respect to the number of Gauss integration points \( n \) is carried out. The SIFs and T-stress are calculated and normalized values are plotted against \( n \) in Fig. 8 for \( n \) ranging from 6 to 20. According to Fig. 6, the crack angle is \( \theta = 30^\circ \) and the lateral load ratio is \( \lambda = 0.5 \). The outer boundary of the plate is discretized with only two quadratic elements on each side, the crack is discretized with 10 elements and \( r/a = 1.0 \). Fig. 8 shows that the results converge when \( n \) is equal to or greater than 8. The T-stress results are more sensitive to the number of integration points \( n \) than the SIFs. For higher values of \( n \) (e.g. \( n > 20 \)), stress results at integration points very close to the crack face are required. Accurate stress evaluation close to the boundary requires appropriate treatment of near-singular integrals. In the present implementation, no special treatment has been considered for this purpose. Instead, by increasing the number of elements to discretize the crack \( (m) \), accurate results are obtained when \( n \) is large. However, for all the other problems presented in this paper the number of integration points \( n \) used was between 8 and 12, which proved sufficient.

5.1.3. Effect of crack discretization

A convergence study on crack discretization with the number of the elements on the crack \( m \) ranging from 2 to 14 elements is done. The crack is oriented at \( \theta = 30^\circ \) and \( \lambda = 0.5 \). The outer boundary of the plate is discretized with only two quadratic elements on each side. The number of Gauss points is \( n = 8 \). The normalized values of \( K_I/K_{I_{\text{exact}}} \), \( K_{II}/K_{II_{\text{exact}}} \) and \( T/T_{\text{exact}} \) are presented in Table 3, which shows that discretizing the crack with four elements is sufficient for the present problem.

5.1.4. Effect of crack-tip elements

The influence of the type of crack-tip elements on the SIFs and the T-stress results is studied. The crack angle is \( \theta = 30^\circ \) and the lateral load ratio is \( \lambda = 0.5 \). The outer boundary of the plate is discretized with only two quadratic elements on each side and the crack is discretized with six elements. The number of Gauss points is \( n = 8 \) and \( r/a = 1.0 \). Table 4 shows normalized SIFs and the T-stress obtained by using standard quadratic elements (Fig. 4(a)), quarter-point elements (Fig. 4(b)) and modified quarter-point elements (Fig. 4(c)) as crack-tip elements. As expected, there is no significant difference in the results, especially for the latter two elements. Since the M-integral

The parameter \( m \) denotes the number of elements on the crack surface.
5.2. Slanted edge crack in a finite plate

Fig. 9 shows a slanted edge crack in a finite plate loaded with a uniform traction $\sigma = 1$ applied symmetrically at the ends. The crack length is $a/W = 0.4\sqrt{2}$ and the plate dimensions are $H = 2W = 1$ (consistent units). $T$-stress, $K_I$ and $K_{II}$ are calculated for the crack angle $\theta = 45^\circ$. The outer boundary of the plate is discretized using 20 quadratic elements on the left side and 10 quadratic elements on rest of the sides. The crack is discretized using six elements ($m = 6$). The number of Gauss points is $n = 10$, and $r/a = 0.5$. The Young’s modulus is taken as $E = 1.0$ (consistent units) and Poisson’s ratio is $\nu = 0.3$. Kim and Paulino solved this problem previously using FEM by the $J_c$-integral [58] and the interaction integral [35]. Table 5 shows a comparison of the present results with those obtained using the $J_c$-integral [58] and the interaction integral method [59]. Here, $a^-$ and $a^+$ refer to the left and right crack-tips, respectively, in Table 6. The present results (SGBEM) agree very well with those by Kim and Paulino [58] and Shbeebe et al. [59].

5.3. Multiple interacting cracks

Fig. 10 shows two cracks of length $2a$ oriented with an angle $\theta_1$ ($\theta_1 = 30^\circ$, $\theta_2 = 60^\circ$) in a finite 2D plate. The distance from the origin of the coordinate system (see Fig. 10) to the two crack-tips which are closer to the origin is computed away from the crack-tip, the details of the local crack-tip interpolation do not have much influence on the results. However, such details are relevant for a local method like the DCT [26].

Fig. 12 shows two cracks of length $2a$ oriented with an angle $\theta$ ($\theta = 45^\circ$) to the two crack-tips which are closer to the origin is

is computed away from the crack-tip, the details of the local crack-tip interpolation do not have much influence on the results. However, such details are relevant for a local method like the DCT [26].

1.0. Kim and Paulino [58] have provided finite element solution and Shbeebe et al. [59] have provided semi-analytical solutions using integral equation method for this problem. The applied load is $\sigma = 1.0$, the crack length is $2a = 2$, the plate dimensions are given by $H/W = 1.0$, $W = 20$, and the material properties are $E = 1.0$, $\nu = 0.0$ (consistent units). The number of integration point is $n = 12$ and $r/a = 1$. The outer boundary is discretized with 10 quadratic elements, and each of the cracks is discretized with 10 elements ($m = 10$). Table 6 shows a comparison of the normalized SIFs at crack-tips for the lower crack oriented at an angle $\theta = 30^\circ$ computed by the present interaction integral ($M$) with those obtained using the $J_c$-integral [58] and the integral equation method [59]. Here, $a^-$ and $a^+$ refer to the left and right crack-tips, respectively, in Table 6. The present results (SGBEM) agree very well with those by Kim and Paulino [58] and Shbeebe et al. [59].

5.4. Various fracture specimen configurations

This final example investigates the $T$-stress and the SIFs for various benchmark fracture specimens, i.e. CCT or MT specimen, the SENT specimen, the SENB specimen, and the DENT specimen as shown in Fig. 11. In order to understand the behaviour of the $M$-integral a plot of the integrand along the integration path $\omega$ from $-\pi$ to $+\pi$ for the SENT specimen with $a/W = 0.5$ is depicted in Fig. 12.

The analyses were carried out using plane strain conditions with Young’s modulus $E = 1.0$ and Poisson’s ratio $\nu = 0.3$. The applied load is $\sigma = 1$ for the different load configurations of Fig. 11 (consistent units). The crack is discretized using 10 elements ($m = 10$). The number of
Gauss integration point is $n = 10$. The outer boundary of the CCT specimen is discretized with 10 quadratic elements on each side, while for the rest of the specimens (SENT, SENB and DENT), the outer boundary is discretized with 50 quadratic elements on the left edge and 30 quadratic elements on the rest of the edges. Only half of the DENT specimen was analysed due to its symmetry. Table 7 shows good agreement between present results (SGBEM) and those available in the literature. Fig. 13 shows the variation of biaxiality ratio $\left(B = T\sqrt{\pi a}K_1\right)$ versus the ratio of crack length to width $a/W$ for various specimens ($H/W = 12$) and compares with the results published by Fett et al. [60] using the boundary collocation method, and by Kim and Paulino [36] using the FEM. Notice that, for the SENB the present solution (SGBEM) is closer to that by Fett et al. [60], while, for the DENT, the present solution (SGBEM) is closer to that by Kim and Paulino [36]. In general, all the solutions (SGBEM, Fett et al. [60], and Kim and Paulino [36]) show very good agreement in Fig. 13. The sign of the biaxiality ratio changes from negative to positive as $a/W$ increases in SENT and SENB, while the sign remains the same for CCT and DENT specimens.

6. Concluding remarks and extensions

The interaction integral method applied to mixed-mode crack problems to evaluate $T$-stress and the SIFs using the SGBEM has been presented. This method provides an accurate and robust scheme for calculating the fracture parameters. The numerical results obtained are in remarkable agreement with known results for single and multiple cracks. In general, the $T$-stress computations are more demanding than those for SIFs (see Figs. 7 and 8). This observation is in agreement with analogous studies in the FEM field—see for example Refs. [36,61].

The influence of several parameters on the SIFs and $T$-stress has been investigated, including the radius of the integration contour ($r$), the number of integration points ($n$), number of elements on the crack surface ($m$), and type of crack-tip elements. Based on the experience acquired with the present study, the number of Gauss points $n = 10$ and number of crack elements $m = 10$ give accurate results for all the problems investigated. A value of $r/a > 0.3$ is sufficient for most problems, except when $a/W$ is large, where $a$ is the length of the crack and $W$ is the width of the plate. A fracture criteria which includes the SIFs and $T$-stress

Fig. 11. Various fracture specimen configurations. The thickness of each specimen is $t$.

Fig. 12. Variation of integrand of the $M$-integral along the integration path with $r/a = 0.5$ where $a$ is the crack length. Parameters adopted: $m = 10$, $n = 10$.

The boundary collocation method, and by Kim and Paulino [36] using the FEM. Notice that, for the SENB the present solution (SGBEM) is closer to that by Fett et al. [60], while, for the DENT, the present solution (SGBEM) is closer to that by Kim and Paulino [36]. In general, all the solutions (SGBEM, Fett et al. [60], and Kim and Paulino [36]) show very good agreement in Fig. 13. The sign of the biaxiality ratio changes from negative to positive as $a/W$ increases in SENT and SENB, while the sign remains the same for CCT and DENT specimens.
can be implemented in the present code and used to predict crack initiation angle (see, for example, Ref. [35]).

A potential extension of this SGBEM work includes development of the two-state integral post-processing approach to 3D crack problems. Another possible extension involves fracture mechanics of non-homogeneous materials, such as FGMs, which can make use of the new Green’s functions developed by Chan et al. [62] in 2D and

Martin et al. [63] in 3D. Such Green’s function approach allow the boundary element solution of fracture problems in FGMs using a boundary-only approach (i.e. no domain discretization).

Acknowledgements

We acknowledge the support from the Computational Science and Engineering (CSE) Program (Prof. Michael Heath, Director) at the University of Illinois at Urbana-Champaign (UIUC) for the CSE Fellowship award to A. Sutradhar. We thank Dr L.J. Gray, Oak Ridge National Laboratory and Prof. Anh-Vu Phan, South Alabama University, for helping us with the 2D SGBEM elasticity code. We also thank Dr J.-H. Kim for providing the SIF results for the slanted edge crack problem obtained by the M-integral method using the FEM and also for useful suggestions. G.H. Paulino acknowledges the support from the National Science Foundation under grant CMS-0115954 (Mechanics and Materials Program).

Appendix A. Auxiliary fields for SIFs

The angular functions \( f_i(\theta) \) in Eqs. (2) and (24) are given by

\[
\begin{align*}
  f^1_1(\theta) &= \cos \frac{\theta}{2} \left( 1 - \sin \frac{\theta}{2} \sin \frac{3\theta}{2} \right), \\
  f^1_2(\theta) &= -\sin \frac{\theta}{2} \left( 2 + \cos \frac{\theta}{2} \cos \frac{3\theta}{2} \right), \\
  f^2_2(\theta) &= \cos \frac{\theta}{2} \left( 1 + \sin \frac{\theta}{2} \sin \frac{3\theta}{2} \right), \\
  f^2_3(\theta) &= \sin \frac{\theta}{2} \cos \frac{\theta}{2} \cos \frac{3\theta}{2}, \\
  f^2_4(\theta) &= \sin \frac{\theta}{2} \cos \frac{\theta}{2} \cos \frac{3\theta}{2}, \\
  f^2_5(\theta) &= \cos \frac{\theta}{2} \left( 1 - \sin \frac{\theta}{2} \sin \frac{3\theta}{2} \right)
\end{align*}
\]

and \( g_i(\theta) \) in Eq. (25) is given by

\[
\begin{align*}
  g^1_1(\theta) &= \frac{1}{4} \left( 2\kappa - 1 \right) \cos \frac{\theta}{2} - \cos \frac{3\theta}{2}, \\
  g^1_2(\theta) &= \frac{1}{4} \left( 2\kappa + 3 \right) \sin \frac{\theta}{2} + \sin \frac{3\theta}{2}, \\
  g^2_1(\theta) &= \frac{1}{4} \left( 2\kappa + 1 \right) \sin \frac{\theta}{2} - \sin \frac{3\theta}{2}, \\
  g^2_2(\theta) &= \frac{1}{4} \left( 2\kappa - 3 \right) \cos \frac{\theta}{2} + \cos \frac{3\theta}{2}
\end{align*}
\]

Appendix B. Displacement derivatives of auxiliary fields for determining the T-stress

\[
\begin{align*}
  u_{1,1}^{\text{aux}} &= -\frac{f \cos \theta}{\pi E r} \left( 1 - \frac{\sin^2 \theta}{1 - \nu} \right), \\
  u_{1,2}^{\text{aux}} &= -\frac{f \cos \theta}{\pi E r} \left( 1 - \frac{\sin^2 \theta}{1 - \nu} \right), \\
  u_{2,1}^{\text{aux}} &= \frac{f \sin \theta}{\pi E r} \left( 1 - \frac{\cos^2 \theta}{1 - \nu} \right), \\
  u_{2,2}^{\text{aux}} &= \frac{f \sin \theta}{\pi E r} \left( 1 - \frac{\cos^2 \theta}{1 - \nu} \right)
\end{align*}
\]  

(AppB1)

where \( E' \) is given by Eq. (23).

Appendix C. Displacement derivatives of auxiliary fields for SIFs

\[
\begin{align*}
  u_{1,1}^{\text{aux}} &= \frac{1}{8\mu\sqrt{2\pi r}} \left[ K_1^{\text{aux}} \left( (2\kappa - 3)\cos \frac{\theta}{2} + \cos \frac{5\theta}{2} \right) - K_0^{\text{aux}} \left( (2\kappa + 1)\sin \frac{\theta}{2} + \sin \frac{5\theta}{2} \right) \right], \\
  u_{1,2}^{\text{aux}} &= \frac{1}{8\mu\sqrt{2\pi r}} \left[ K_1^{\text{aux}} \left( (2\kappa + 3)\sin \frac{\theta}{2} + \sin \frac{5\theta}{2} \right) - K_0^{\text{aux}} \left( (2\kappa - 1)\cos \frac{\theta}{2} - \cos \frac{5\theta}{2} \right) \right], \\
  u_{2,1}^{\text{aux}} &= \frac{1}{8\mu\sqrt{2\pi r}} \left[ K_1^{\text{aux}} \left( (2\kappa + 1)\cos \frac{\theta}{2} + \cos \frac{5\theta}{2} \right) + K_0^{\text{aux}} \left( (2\kappa + 5)\cos \frac{\theta}{2} + \cos \frac{5\theta}{2} \right) \right], \\
  u_{2,2}^{\text{aux}} &= \frac{1}{8\mu\sqrt{2\pi r}} \left[ K_1^{\text{aux}} \left( (2\kappa - 1)\cos \frac{\theta}{2} - \cos \frac{5\theta}{2} \right) + K_0^{\text{aux}} \left( (2\kappa - 5)\sin \frac{\theta}{2} + \sin \frac{5\theta}{2} \right) \right]
\end{align*}
\]  

(AppC1)

Appendix D. Integration of the singular terms in M-integral for calculating the T-stress

The contribution of the singular terms in the M-integral for calculating the T-stress is evaluated. Let

\[
M = \int_{\Gamma} \left[ (\sigma_{ik} e_{ik}^{\text{aux}} n_1 - (\sigma_{ij} e_{ij}^{\text{aux}} + \sigma_{ij}^{\text{aux}} u_i n_j) d\Gamma \right].
\]  

(D1)

By selecting a circular integration path, the coefficients of the singular terms \( O(r^{1/2}) \) from the integration over \( \theta \) from \(-\pi\) to \(+\pi\) in Eq. (D1) are evaluated. After integration, the first, second and the third term of Eq. (D1) yield

\[
\int_{-\pi}^{\pi} \sigma_{ik} e_{ik}^{\text{aux}} n_1 d\theta = -\frac{1}{210} \frac{\sqrt{2}K_u(49\kappa - 27)}{\pi \sqrt{r \pi \mu}}.
\]  

(D2)
\[ \int_{\Gamma} \sigma_{ij} u_i \, d\theta = -\frac{1}{105} \frac{f_2 K_i (7 \kappa + 3)}{\pi \sqrt{r \pi \mu}}, \quad (D3) \]

and

\[ \int_{\Gamma} \sigma_{ij}^\text{aux} u_i \, d\theta = -\frac{1}{10} \frac{f_2 K_i (3 \kappa - 1)}{\pi \sqrt{r \pi \mu}}, \quad (D4) \]

respectively. These three terms add to zero.
